ASCO Perspective
“This study provides strong evidence to support adding abiraterone to standard hormone therapy, primarily for men with metastatic prostate cancer,” said Sumanta Kumar Pal, MD, ASCO Expert.
“It adds to a growing body of evidence that establishes abiraterone as a standard of care in this setting.”

CHICAGO – A clinical trial of nearly 2,000 men shows that adding abiraterone acetate (Zytiga) to a standard initial treatment regimen for high-risk, advanced prostate cancer lowers the relative risk of death by 37%. The 3-year survival rate was 76% with standard therapy alone, but 83% with standard therapy plus abiraterone. This is the largest study of abiraterone as first-line therapy for advanced prostate cancer.

The study will be featured in a press briefing today and presented at the 2017 American Society of Clinical Oncology (ASCO) Annual Meeting.

“Abiraterone not only prolonged life, but also lowered the chance of relapse by 70% and reduced the chance of serious bone complications by 50%,” said lead study author Nicholas James, BSc, MBBS, PhD, Professor of Clinical Oncology at Queen Elizabeth Hospital in Birmingham, United Kingdom. “Based on the magnitude of clinical benefit, we believe that the upfront care for patients newly diagnosed with advanced prostate cancer should change.”

Testosterone fuels the growth of prostate cancer cells. Androgen deprivation therapy or ADT slows prostate cancer growth by preventing testicles from making testosterone and other similar hormones (androgens). Despite ADT, other organs in the body, including the prostate gland, continue to make small amounts of testosterone and other androgens. Abiraterone stops production of both testosterone and other androgens throughout the body by targeting an enzyme
that converts other hormones to androgens.

About the Study
STAMPEDE is an ongoing multi-arm, multi-stage randomized clinical trial conducted in the United Kingdom and Switzerland. The current analysis compared standard therapy with standard therapy plus abiraterone in men with high-risk prostate cancer who were starting ADT. The men had either locally advanced or metastatic cancer, and all were commencing long-term standard ADT for the first time. The standard therapy consisted of ADT for at least two years; men with locally advanced cancer (48% of all patients) could also receive radiation therapy in addition to ADT.

A novel approach to clinical trial design meant that this comparison recruited patients much more quickly than most academic-led trials, and STAMPEDE will report randomized data from at least 10 comparisons over two decades.

Key Findings
At a median follow up of 40 months, 262 deaths had occurred in the standard therapy group and 184 in the abiraterone group. The three-year overall survival rate was 83% in the abiraterone group vs. 76% in the standard therapy group. Abiraterone lowered the relative chance of treatment failure (measured by worsening scans or symptoms, or elevated PSA level) by 71% compared to standard therapy. The effects were consistent across the different subgroups of people enrolled in the trial.

Overall, side effects were similar between the two groups. Severe side effects were more common in the abiraterone group, occurring in 41% of patients compared to 29% of patients in the standard therapy group. The main side effects occurring more frequently with abiraterone were cardiovascular problems such as high blood pressure; there were also more liver problems. There were two treatment-related deaths in the abiraterone group and one in the standard therapy group.

Next Steps
Findings from three prior clinical trials showed a similar benefit from adding chemotherapy docetaxel (Taxotere) to initial ADT for men with metastatic prostate cancer. Research is needed to see if these two treatments could be combined so patients can have the benefits of both drugs. For now, this is not known, and the researchers are planning molecular analyses of tissue samples collected in the study to see if a subset of patients would benefit more from adding either docetaxel or abiraterone. Data from the study are also contributing to indirect comparison of outcomes with adding docetaxel, abiraterone, and other treatments using a “network meta-analysis” approach.

“It is possible that certain patients who have a fast-growing cancer might benefit from a
combination of abiraterone and docetaxel, but we need more research to confirm that,” said Dr. James.

This study was funded by grants from Cancer Research UK, Medical Research Council, and Janssen, with additional contributions to the STAMPEDE protocol from Astellas, Clovis Oncology, Janssen, Novartis, Pfizer, and Sanofi-Aventis.

About ASCO:

Founded in 1964, the American Society of Clinical Oncology, Inc. (ASCO®) is committed to making a world of difference in cancer care. As the world’s leading organization of its kind, ASCO represents more than 40,000 oncology professionals who care for people living with cancer. Through research, education, and promotion of the highest-quality patient care, ASCO works to conquer cancer and create a world where cancer is prevented or cured, and every survivor is healthy. ASCO is supported by its affiliate organization, the Conquer Cancer Foundation. Learn more at www.ASCO.org, explore patient education resources at www.Cancer.Net, and follow us on Facebook, Twitter, LinkedIn, and YouTube.
